

Object Storage and MinIO

MinIO is a high-performance, S3-compatible object storage server. In a RAG data pipeline it acts as the durable home for raw uploaded files: the upload service writes each incoming document to a MinIO bucket and immediately returns, while a background worker later fetches the object, extracts its text, chunks it, and stores embeddings in the vector database.

Because the original bytes stay in object storage, the pipeline can always reprocess documents from scratch - for example after changing the chunk size or upgrading the embedding model - without asking anyone to upload again.
